Work in [18] employs a transformer-based approach as a fully end-to-end object detector, delving into the connections between objects and the overall image context for object detection. There are several transformer-based models designed for a specific task [20], [21], [22], [23]. While the transformer method is good at capturing global context, it struggles to grasp fine-grained details, especially for medical images. Efforts have been made to integrate CNN- and Transformer-based models into each other [24], [25]. In particular, TransUNet [29] [27], [28]. In particular, TransUNet and TransFuse are representative examples of combining the transformer and UNet for medical image segmentation.
